

During the recall from a cloud tier NetWorker might use any (other) pool

My test environment once again was:

- NetWorker 19.7.0.0
- Data Domain DDVE 7.7.0.0
- ECS-CE 3.7.0.0

During my restore tests from an ECS media I noticed that the save set might not be migrated back to the same pool from which it had been cloned to the cloud tier.

This might confuse you. However, this is NetWorker's way to support a restore a.s.a.p. without the necessity to wait for a specific device/media.

And btw - these recalled save sets by default have a retention period of 7 days. So in a true production environment they will disappear again after this time and not harm at all - you might not even become aware where they have been moved to.
